INTRODUCTION AND AIMS

In autosomal recessive polycystic kidney disease (ARPKD), progressive enlargement of fluid-filled cysts is due to aberrant proliferation of tubule epithelial cells and transepithelial fluid secretion leading to extensive nephron loss and interstitial fibrosis. Congenital hepatic fibrosis associated with biliary cysts/dilatations is the most common extrarenal manifestation in ARPKD, and can lead to massive liver enlargement. Peroxisome proliferator-activated receptor- γ (PPAR- γ), a member of the ligand-dependent nuclear receptor superfamily, is expressed in a variety of tissues, including the kidneys and liver, and plays important roles in cell proliferation, fibrosis and inflammation. In the current study, we determined that pioglitazone (PIO), a PPAR- γ agonist, decreases polycystic kidney and liver disease progression in the PCK rat, an orthologous model of human ARPKD.

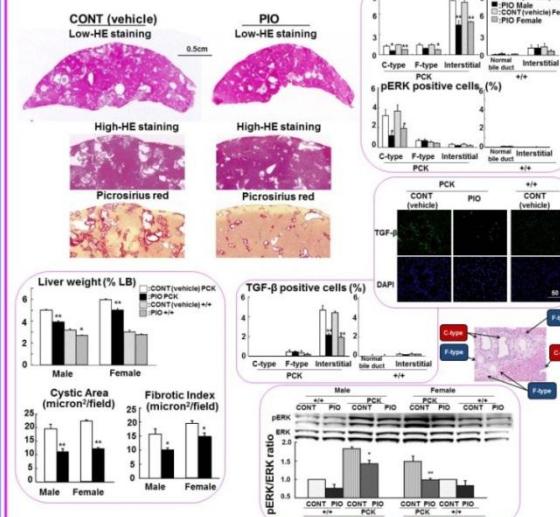

Results in the kidney

Daily treatment with 10 mg/kg PIO for 16 weeks decreased kidney weight (%KB), renal cystic area, SUN and the number of Ki67-, pERK1/2- and pS6-positive cells in the kidney. Body weight, food and water intake, fibrotic index and the number of TGF- β of gender-matched PCK and +/+ rats did not differ at 20 weeks of age and was unaffected by treatment with PIO.

Results in the Liver

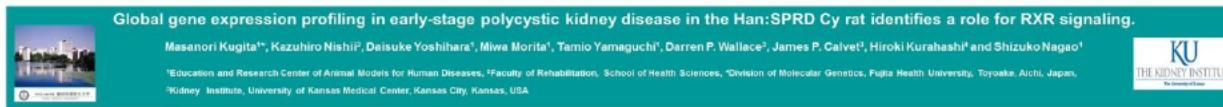

PIO-treatment decreased liver weight (%LB), liver cystic area, fibrotic index, and the number of Ki67-, pERK1/2-, pERK5- and TGF- β -positive cells in the liver. Blood sugar levels, serum AST, total bilirubin levels and the number of pS6 of gender-matched PCK and +/+ rats did not differ at 20 weeks of age and was unaffected by treatment with PIO.

CONCLUSIONS

The PPAR- γ agonist PIO ameliorates polycystic kidney disease in association with inhibition of the ERK and mTOR signaling pathways, and fibrocytic liver disease in association with inhibition of the ERK and TGF- β signaling pathways in PCK rats, an orthologous model of human ARPKD. These data support the use of PPAR- γ agonists as therapeutic agents for the treatment of polycystic kidney and liver disease in ARPKD patients.

Abstract

Expression profiles of 41,324 genes were determined by microarray analysis. The expression levels of each gene were normalized to the mean expression level of all genes in the samples. The expression levels of each gene were then converted to a log₂ scale relative to the mean expression level of all genes in the samples.

Fig. 2. Comparison of the gene expression on p53Rb. Each panel shows a single gel. Vertical axis indicates the ratio of expression of genes in each genotype. Left panel shows results from the kidneys of 7-day-old rats. Line over 1.0 indicates up-regulated genes and line under 1.0 down-regulated genes. The numbers of genes detected as 15-fold changes in each genotype corresponded to 15-fold changes in all samples in parenthesis.

Taken together, cell proliferation and cell differentiation signals controlled by RXR-mediated pathways may have important roles during cytotogenesis in the early developmental stages of PKD in Pkd¹ mice.

Materials & Methods

Non-SPRO +/+ , Cx4+ and Cx/Cy rats were analyzed at 3 and 7 days of age.

- Hematoxylin and Eosin (HE) staining
- To elucidate mechanism of cyst formation, we investigated by
 - DNA microarray analysis
 - Using Agilent Rat oligo Microarrays (product no. G4130A)
 - Canonical pathway (CP) analysis by Ingenuity Pathway Analysis (IPA) ver. 6.0
 - Gene ontology (GO) analysis by GeneSpring GX 7.3

Result

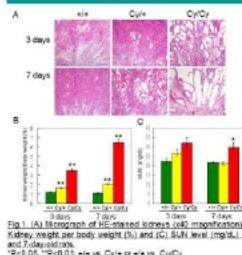

Fig. 4. Outline of GO analysis for elucidating functional categories. The GO analysis derived 281 functional categories from 83 genes of 3-day-old kidneys and 413 functional categories from 204 genes of 7-day-old kidneys ($P < 0.001$). Fifteen GO categories were in common between 30 categories of 3-day ($P < 1.00E-03$) and 33 categories of 7-day-old kidneys.

($P < 1.00E-05$) Cy/Cy kidneys.

Table 1. Genes regulated by RXR α (NR α or TR β) that were in common between 3-day and 7-day CHOC kidneys.

going forward on each G0 category

Table 3. Selected genes involved in RXR regulation of cell proliferation and tissue morphogenesis that were altered in 3-day and 7-day Gyr/Gy kidneys.

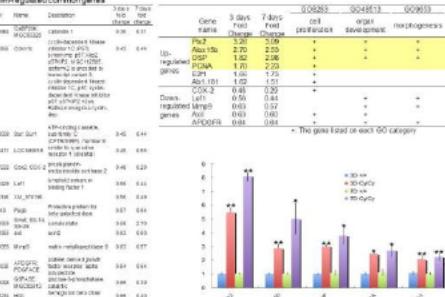

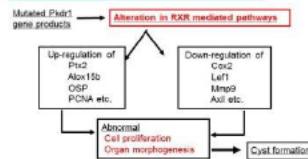

Fig. 5. Relative expression of selected genes in Cy/Cy rats compared to +/+ rats determined by RT-PCR.
*P<0.05, P<0.01 age-matched +/+ vs. Cy/Cy.

Conclusions

Current results suggest that cell proliferation and organ morphogenesis signals transduced by RXR mediated pathways may have important roles for the cystogenesis in early stage of PKD in Han:SPRD Cy rats.

多発性囊胞腎症(PKD)の早期診断・治療マーカーの開発

腎臓をはじめとする全身の諸臓器に多数の囊胞が発生する多発性囊胞腎症(PKD)は、人口1,000人に1人の患者が存在し、遺伝性疾患として極めて高い発症率を示します。患者の半数が慢性腎臓病(CKD)から末期腎不全(ESRD)に陥るために、人工透析や腎移植が必要となるばかりではなく、心血管疾患の発症リスクも高くなります。

そこで私共の研究グループでは、東北大大学阿部高明教授および慶應義塾大学曾我朋義教授と共に、キャピラリー電気泳動-質量分析計を用いて、藤田保健衛生大学で維持しているPKD疾患モデル動物の血中尿毒症物質を明らかにし、PKDに固有な診断・治療マーカーを発見しました。この新しいマーカーを用いることで、本疾患の治療薬の開発にも大きく貢献することができます。

[開発者のメッセージ]

PKDの患者様にとって、早期の診断・治療マーカーや有効な治療薬が少ないと大きな負担となっております。新たなマーカーの発見によって、早期の治療開始を可能にすると共に、新たな治療薬開発の迅速化に繋げたいと考えます。

Graduate Seminar Series - Human Nutritional Sciences

Date: Tuesday, November 15, 2011

Time: 3:00 PM – 5:00 PM

Location: Room 207 Human Ecology Building

The Department of Human Nutritional Sciences invites you to a talk by Dr. Shizuko Nagao. The presentation is entitled "Therapeutic approaches in animal models of polycystic kidney disease: Effect of PPAR-gamma agonists on disease progression"

Dr. Nagao is the Director, Education and Research Centre of Animal Models for Human Diseases and an Associate Professor in Fujita Health University
